

Global Warming

Research shows that global warming is caused by human activity. What are the possible effects of climate change and what can governments and individuals do to reduce these?

There is now little doubt that global warming and climate change are the result of human activity. This has happened because of a failure in environmental policy by governments and a lack of concern for wasted energy by individuals.

It is almost universally accepted that climate change is the consequence of a number of environmental failings. Perhaps the most important of these is how fossil fuels such as gas and coal are still the main source of power. This is a problem because their use means that a large amount of CO₂ is released into the atmosphere causing the greenhouse effect. Another serious issue is how illegal logging continues in rainforests and the Amazon Basin in particular. It should also not be forgotten that there is a connection between global warming and the inefficient use of energy by consumers in the home.

While governments must take prime responsibility for reducing climate change, individuals too can play a part. Political leaders across the globe need to cooperate so that research into renewable forms of energy such as wind and solar power is properly funded and the use of coal and gas in power stations is phased out. They must also of course ensure that regulations against logging are properly enforced. Consumers of energy can help by insulating their homes properly and using solar panels where possible so that less energy is required and wasted. These actions should limit the amount of CO₂ in the atmosphere and so reduce the greenhouse effect.

In conclusion, while global warming is a serious threat to humanity, there are a number of steps that can be taken to reduce its effects.
